market_exposed_max

equity strategy | family: equity-aggressive | status: research | derived from `market_exposed`

What this strategy does

market_exposed with bigger bets for more return: base unit 0.006, 6x leverage cap

Why it should work. Let net exposure float with the signal; empirically this smuggles in uncontrolled market beta.

Design notes (from the strategy's source file).

Aggressive-sizing variants of the hand-built equity strategies.

Same signal, trim, tilt and neutralization as each base strategy; only the two dials that set how big and how levered the book is change (base_unit_fraction, gross-leverage cap = 6x). The multiplier for each was picked by sweeping 1.5x..12x the original base unit and taking the highest return subject to Sharpe >= 0.6 and max drawdown >= -40% (a worse drawdown is a fund-ending event, not a risk preference). The untouched 5%-of-ADV liquidity cap remains the real capacity constraint, and bites roughly four times as often at this sizing.

These are generated from the base strategy classes, so a change to a base strategy's weights flows through automatically.

parameter	value
base_unit_fraction	0.006
max_gross_leverage	6.0
liquidity_cap_frac	0.05
return_basis	raw
cap_mode	priority
beta_overlay	0.0

Performance

metric	market exposed max	market (CRSP VW)
Annualized return	11.78%	9.94%
Annualized volatility	11.85%	19.35%
Sharpe (NAV-pct)	1.00	0.59
Sortino	1.45	
Max drawdown	-33.0%	-55.5%
Calmar	0.36	
Final NAV ($10M start)	$87,451,313	
Worst day	-7.17%	
% positive days	51.9%	
Sharpe 1996-2001	1.64	
Sharpe 2002-2007	1.65	

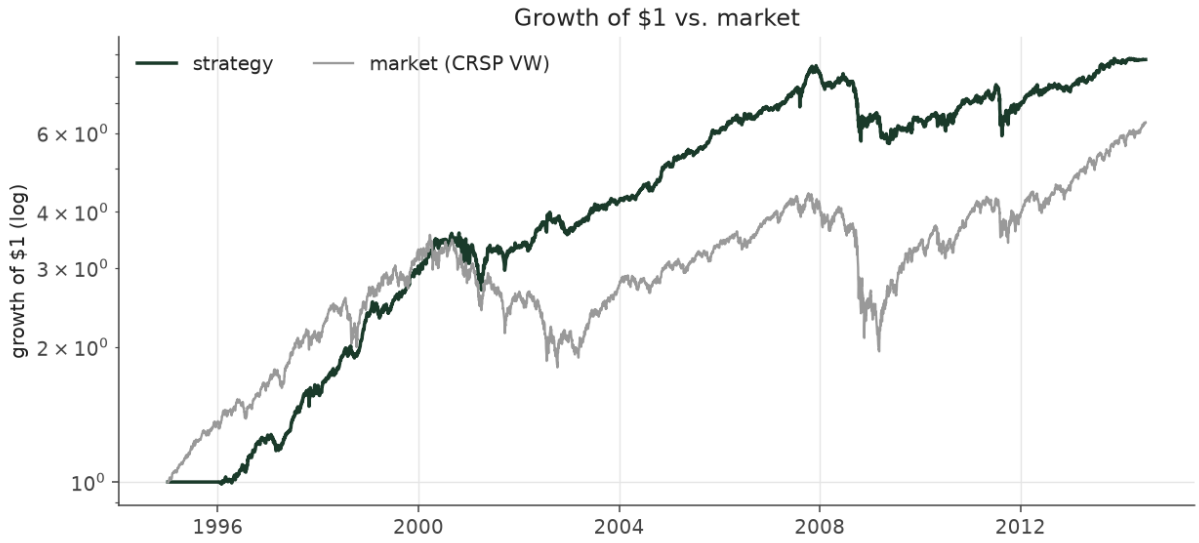

Sharpe 2008-2013	0.13	

Correlation of daily returns with the market: **0.66**.

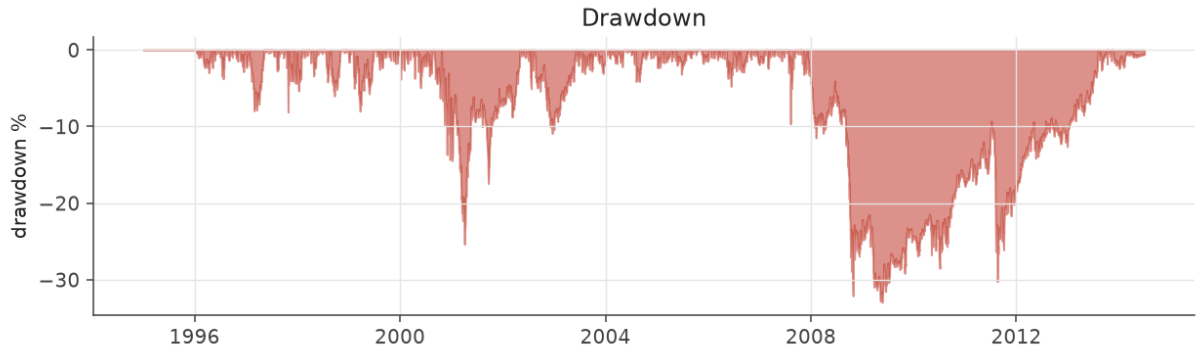

• best Sharpe among equity: `calm_rank_tilt` (1.81); this one: 0.999

• best return among equity: `market_boost_max` (0.15); this one: 0.118

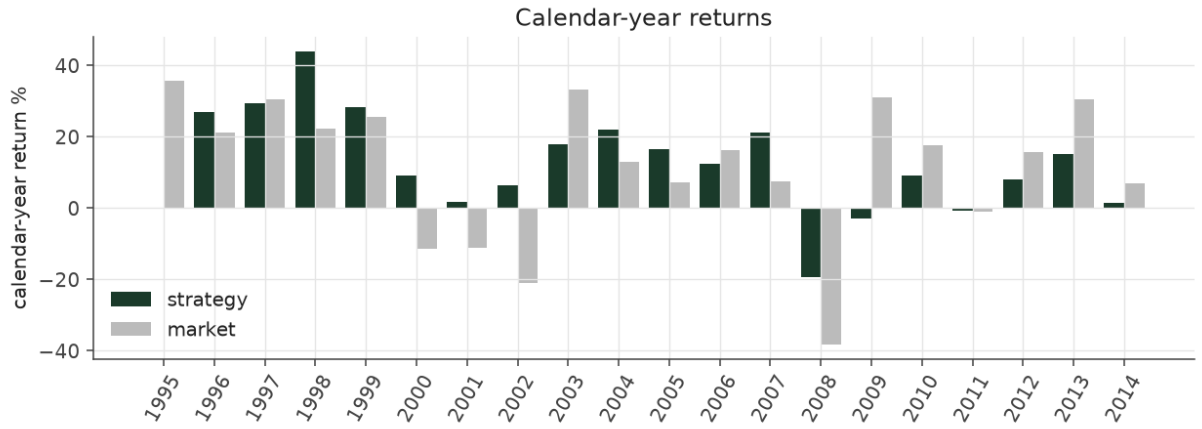

• best Calmar among equity: `calm_rank_tilt` (0.614); this one: 0.357

NAV (log scale)

Drawdown from running peak

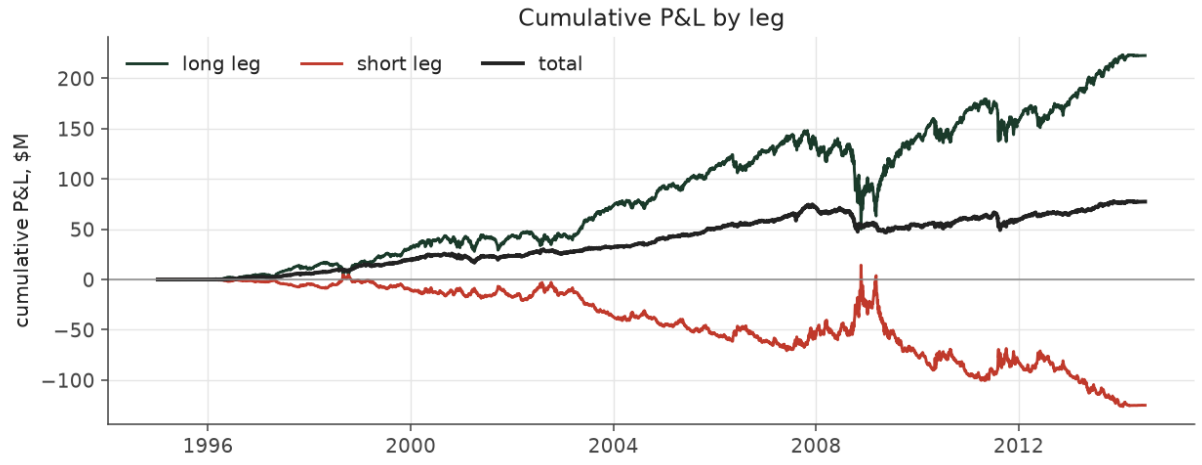

Calendar-year returns

Is the edge stable, or concentrated in a few years?

Where the return comes from

Long leg vs. short leg vs. total

	long leg	short leg
P&L ($M, before costs)	222.73	-124.99
P&L after costs ($M)	212.73	-135.28
of which common (average-event) component ($M)	88.48	-80.08

of which excess / PEAD component ($M)	20.72	48.19
excess minus costs ($M)	10.72	37.90
gross return per $ traded (bp)	370.11	-222.37
positions in the money (hit rate)	0.63	0.42
stand-alone Sharpe (leg only)	0.73	-0.46

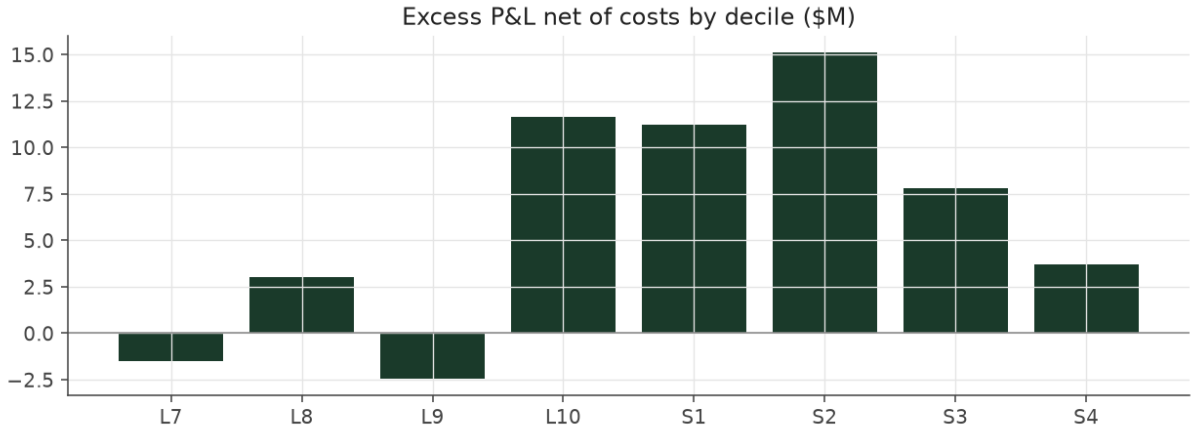

Daily P&L correlation between the two legs: **-0.97**.

• **The short leg loses money in absolute terms** (-125.0M before costs) while the long leg earns +222.7M. That is mostly a benchmark effect, not a signal failure: the average earnings-event stock beat the cap-weighted market during its holding window, which flatters the long leg and hurts the short leg by 88.5M / 80.1M. Stripping that common component, the surprise signal itself earned +20.7M on the long side and +48.2M on the short side.

• The two legs' daily P&L are -0.97 correlated: the short leg is the hedge that makes the long leg's variance disappear (stand-alone leg Sharpe 0.73 long / -0.46 short vs 1.00 combined).

By decile and side (signal-driven part only)

leg	decile	positions	notional M	net pnl M	excess M	cost M	alpha net M	alpha share	alpha bp per $
long	7	8,029	514.45	18.09	-0.60	0.88	-1.49	-3.1%	-28.94
long	8	16,588	1,409.31	53.03	5.42	2.38	3.04	6.3%	21.59

5.0%	55.4	6.16%	5.62%

The engine charges the same transaction cost on shorts as on longs and no stock-borrow fee. The short leg is concentrated in small, illiquid names, where borrow is scarce and expensive -- read the table as a floor on the cost of running the short leg.
