market_boost_max

equity strategy | family: equity-max | status: research | derived from `balanced_leverage_max`

What this strategy does

Balanced Leverage Max plus the same half-size market position

Why it should work. Market-neutral earnings drift with enough gross exposure to matter; the neutrality is the hedge.

Design notes (from the strategy's source file).

Max-size variants ("<name>_max") of the hand-built equity strategies.

Same signal, trim, tilt and neutralization as each base strategy; only the two dials that set how big and how levered the book is change (base_unit_fraction, gross-leverage cap = 6x). The multiplier for each was picked by sweeping 1.5x..12x the original base unit and taking the highest return subject to Sharpe >= 0.6 and max drawdown >= -40% (a worse drawdown is a fund-ending event, not a risk preference). The untouched 5%-of-ADV liquidity cap remains the real capacity constraint, and bites roughly four times as often at this sizing.

These are generated from the base strategy classes, so a change to a base strategy's weights flows through automatically.

parameter	value
base_unit_fraction	0.012
max_gross_leverage	6.0
liquidity_cap_frac	0.05
return_basis	mktadj
cap_mode	priority
exposure_cap	open_book
beta_overlay	0.5

Performance

metric	market boost max	market (CRSP VW)
Annualized return	11.62%	9.94%
Annualized volatility	13.96%	19.35%
Sharpe (NAV-pct)	0.86	0.59
Sortino	1.24	
Max drawdown	-44.6%	-55.5%
Calmar	0.26	
Final NAV ($10M start)	$85,007,236	
Worst day	-5.64%	
% positive days	54.8%	

Sharpe 1996-2001	1.17	
Sharpe 2002-2007	1.48	
Sharpe 2008-2013	-0.05	

Correlation of daily returns with the market: **0.68**.

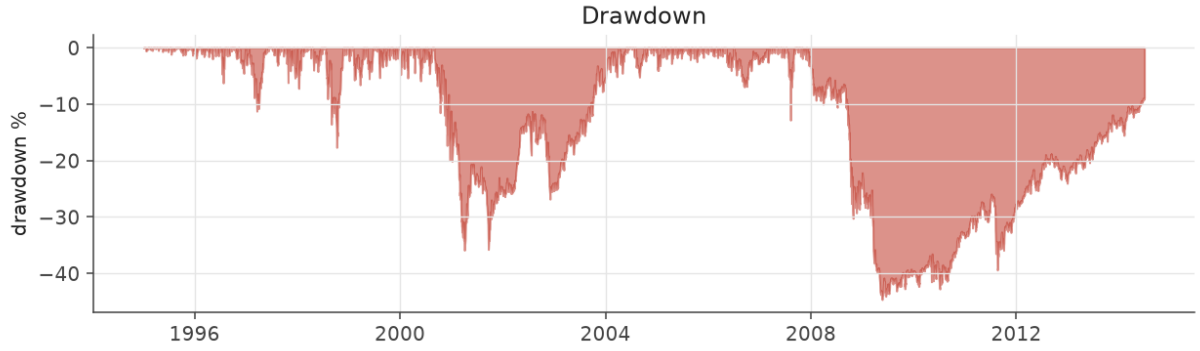

• best Sharpe among equity: `calm_rank_tilt` (1.47); this one: 0.857

• best return among equity: this strategy; this one: 0.116

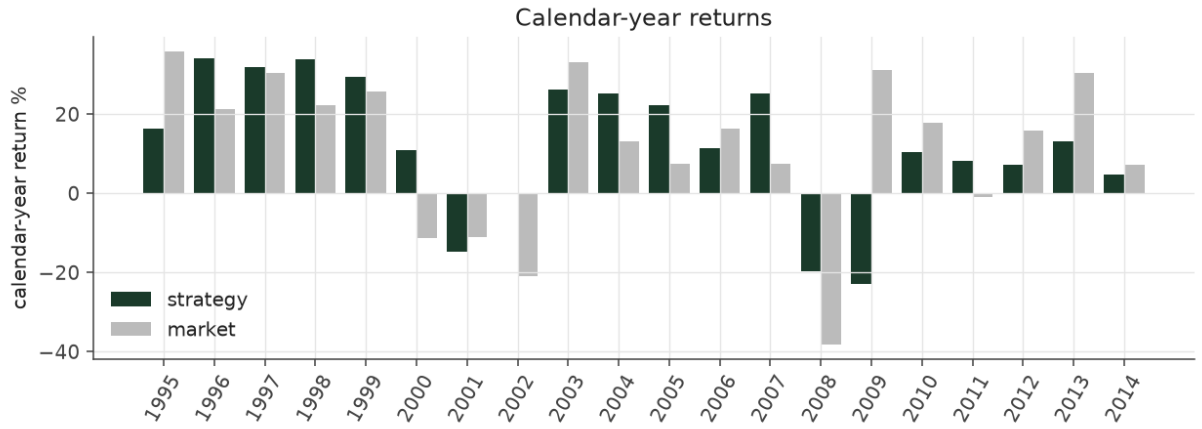

• best Calmar among equity: `calm_rank_tilt` (0.442); this one: 0.26

NAV (log scale)

Drawdown from running peak

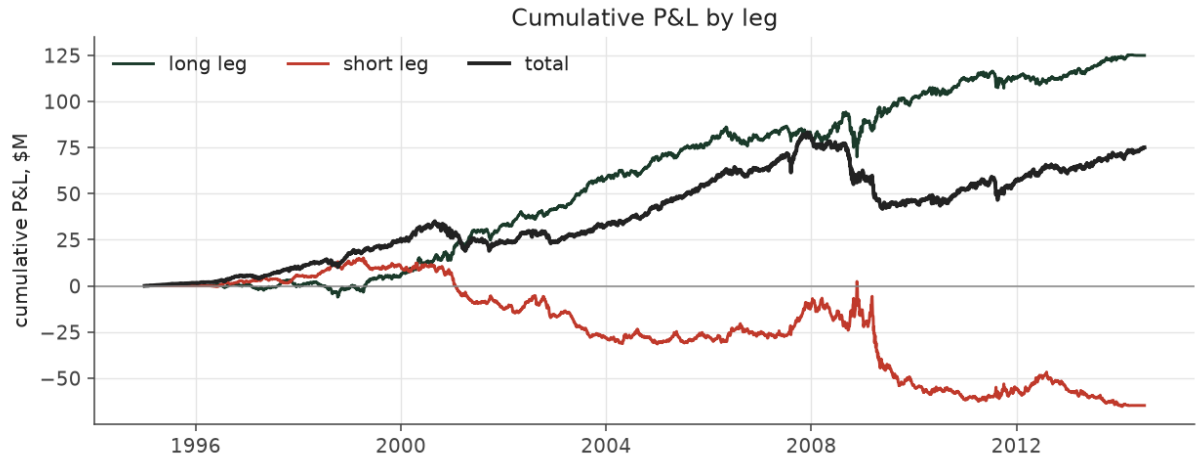

Calendar-year returns

Is the edge stable, or concentrated in a few years?

Where the return comes from

Long leg vs. short leg vs. total

	long leg	short leg
P&L ($M, before costs)	124.90	-64.83
P&L after costs ($M)	114.04	-76.37
of which common (average-event) component ($M)	119.86	-122.72

of which excess / PEAD component ($M)	5.05	57.89
excess minus costs ($M)	-5.82	46.35
gross return per $ traded (bp)	177.22	-88.04
positions in the money (hit rate)	0.55	0.48
stand-alone Sharpe (leg only)	0.99	-0.40

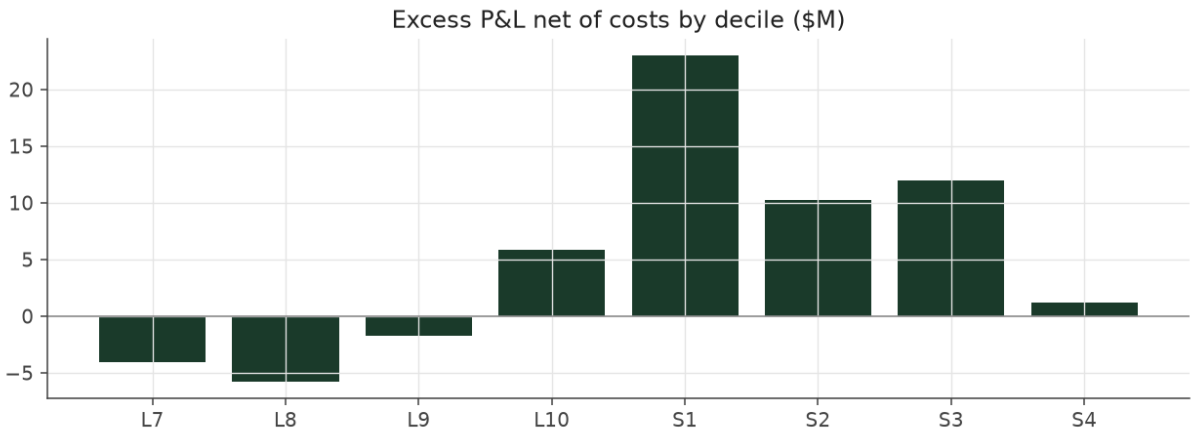

Daily P&L correlation between the two legs: **-0.74**.

• **The short leg loses money in absolute terms** (-64.8M before costs) while the long leg earns +124.9M. That is mostly a benchmark effect, not a signal failure: the average earnings-event stock beat the cap-weighted market during its holding window, which flatters the long leg and hurts the short leg by 119.9M / 122.7M. Stripping that common component, the surprise signal itself earned +5.0M on the long side and +57.9M on the short side.

• The two legs' daily P&L are -0.74 correlated: the short leg is the hedge that makes the long leg's variance disappear (stand-alone leg Sharpe 0.99 long / -0.40 short vs 0.86 combined).

By decile and side (signal-driven part only)

leg	decile	positions	notional M	net pnl M	excess M	cost M	alpha net M	alpha share	alpha bp per $
long	7	3,244	418.72	3.15	-3.46	0.66	-4.11	-10.1%	-98.22
long	8	11,112	1,487.56	22.24	-3.49	2.32	-5.81	-14.3%	-39.07

5.0%	70.7	1.86%	9.76%

The engine charges the same transaction cost on shorts as on longs and no stock-borrow fee. The short leg is concentrated in small, illiquid names, where borrow is scarce and expensive -- read the table as a floor on the cost of running the short leg.
